

A practical journey into Linux system programming for developers, hackers, and curious minds.

Programs do not run in isolation. They execute inside an environment shaped by users, permissions, localization, authentication, and system configuration.

This volume examines the Linux execution environment through time functions, environment variables, locale handling, user and group databases, password management, login systems, and PAM authentication. Each topic is supported by practical code examples that reveal how applications interact with the operating system.

Ideal for novice developers and low-level programmers who want to understand how Linux systems identify, authenticate, and manage processes and users.
