

Build real understanding of Linux through code, debugging, and system internals.

Memory is where programs come alive.

This volume provides a deep exploration of Linux memory management, from dynamic allocation and memory mapping to protection mechanisms, shared objects, and executable loading. It also includes a detailed study of the ELF format and the complete lifecycle of a Linux process in memory.

Combining theory, debugging techniques, and real executable examples, the book helps programmers and hackers understand how software is loaded, organized, protected, and executed by the operating system.

A practical guide to writing code with a real understanding of what happens beneath the surface.
