

**Designed for programmers who want to understand  
what happens behind the abstractions.**

Processes, threads, signals, timers, synchronization, security, and scheduling form the foundation of modern Linux software.

This volume explores how Linux creates, controls, isolates, and coordinates execution. From fork and execve to threads, seccomp, signals, and daemon processes, readers learn how complex applications operate internally and interact with the kernel.

Designed for both newcomers and advanced programmers, the book focuses on practical code, runtime behavior, debugging, and real-world programming patterns used in modern systems software.
